

5) What are the OOPs concepts available in C++?

- Object
- Class
- Inheritance
- Encapsulation
- Abstraction
- Polymorphism
- **Object**
- Any entity which has its own characteristics and behaviors is called as an object.
- **Example:** Car is an object which has color, size as its characteristics and driving, applying brakes as its behaviors.
-
- **Class**
- Class is like a blueprint of an object. It is used for creating objects and initialize member variables.
-
- **Inheritance**
- Inheritance allows one class to acquire all properties of another class. The class which acquire all properties is called as child or derived class. The class using which the properties can be acquired is called as parent or base class. The main usage of Inheritance is, we can reuse the code from the existing parent class.
-
- **Encapsulation**
- It is the process of combining data and functions. Using which direct access of data is not possible. The access is given only using the functions of the respective class.
-
-

- **Abstraction**

- Abstraction is the process of hiding the implementation of any application from outside world.

-

- **Polymorphism**

- Polymorphism refers to many forms, which enables an application to change its behavior during compile and run time.
