

OOPS

Object Oriented programming it means set of rules, principles of guidelines.

Any programming language which follow oops rules in their application development

Such Language its oops language.

CLASS

Classes - blueprint, model, Template, Design.

or class its group of member data and member function which share common relationship.

OBJECT

Object its data

Object implementation of class rules, its physical implement it takes actual memory.

Object its primary runtime entity.in object oriented programming.

or

object its identifiable entity which common characteristics and behavior .

ENCAPSULATION :

(data hiding)wrapping/binding/grouping of related data which its related functionalities .
are known as encapsulation.

ABSTRACTION→

showing essential/required feature/details and hiding background details and functionalities.

INHERITANCE →reuse, rewrite and extends properties of one class into another class.

POLYMORPHISM → Ability to perform more then one forms.

OVERLOADING --

- 1.)same name of method
- 2.)but number of argument/type of argument/order of argument different.
- 3.)same name but different signature.
- 4.)inheritance not rquired.
- 5.)static compile time binding.

OVERRIDING--

- 1.)same name of method.
- 2.)but number of argument/type of argument/order of argument different.
- 3.)same signature.
- 4.)inheritance its must.
- s.)runtime/dynamic binding.

FILE HANDLING → its used to store data permanently , persistently .

FILE →group of sequence of bytes/stream of bytes. type- textfile, binaryfile.

Exception handling → to tell cause of exception(runtime error) and avoid abnormal.
program termination,rest lines of code work fine.

RECURTION → function calling itself,its an alternative of looping.

FUNCTION →

large or complex program may divide into small and easily manageable parts these parts known as function or method.

or function its named block which often receives and return value.

ARRAY → ARRAY its group of similar type of data.

list ---> its group of objects, objects and objects may or may not be same.

POINTER = pointer its special variable which deal with same type of address.

CONTROL STATEMENT== control statement are used to control part of program.

packages → a package is a namespace/directory/folder or folder structure, that organizes a set of related classes, interfaces and enumeration.

SUB-PACKAGE-→

package is the group of related classes and interfaces and enumeration or sub-package as a single unit.

absolute path : path given by programmer where file create.

relative path : when path not passed by programmer its location by default where source file exist.

CONSTRUCTOR →

constructor its special member function of class, it is use to initilize primary value of an objet.

DISTRUCTOR → Its special member function of class,

it is used to deinitialize memory and resourced occupied by an object.
